Hash Tables: Rehashing

Goals

Know how and why to grow and shrink the capacity of a hash table by resizing the array and **rehashing** its contents.

Be prepared to implement rehashing so it runs in worst-case $O(C + n)$.

Load Factor: Performance Implications

$$\text{Load factor } \lambda = \frac{\text{\# entries in table}}{\text{size of the array}}$$

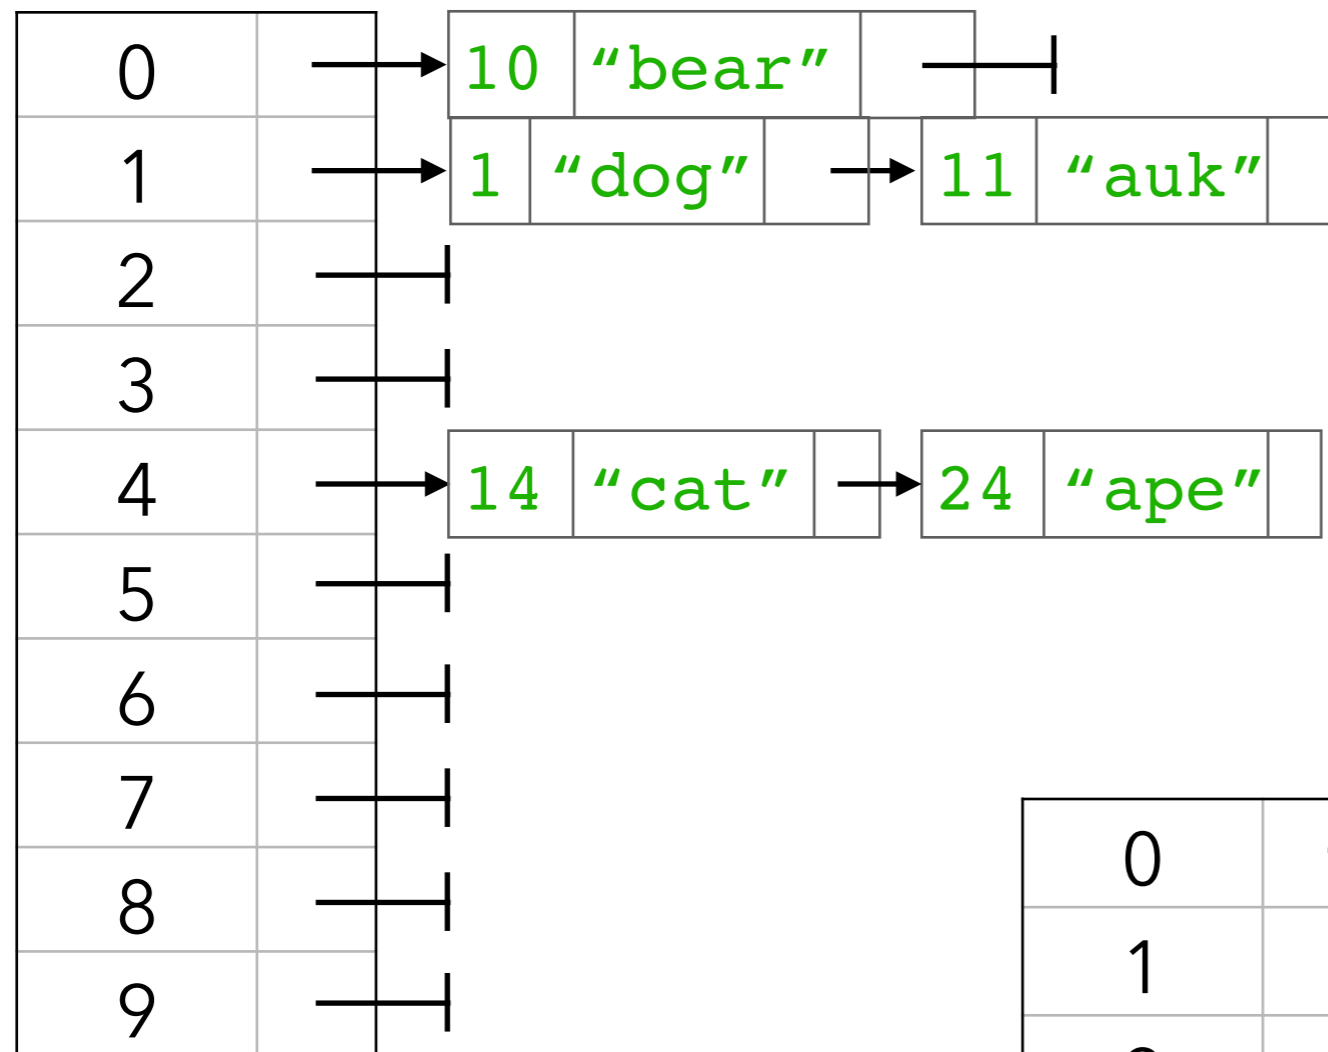

If λ is large, runtime is slow.

If λ is small, memory is wasted.

Strategy: grow or shrink array when λ gets too large or small.

Shrinking the array

Need to **rehash**: put each element where it belongs in the new array.

$$(10 \% 3) \rightarrow 1$$

$$(1 \% 3) \rightarrow 1$$

$$(11 \% 3) \rightarrow 2$$

$$(14 \% 3) \rightarrow 2$$

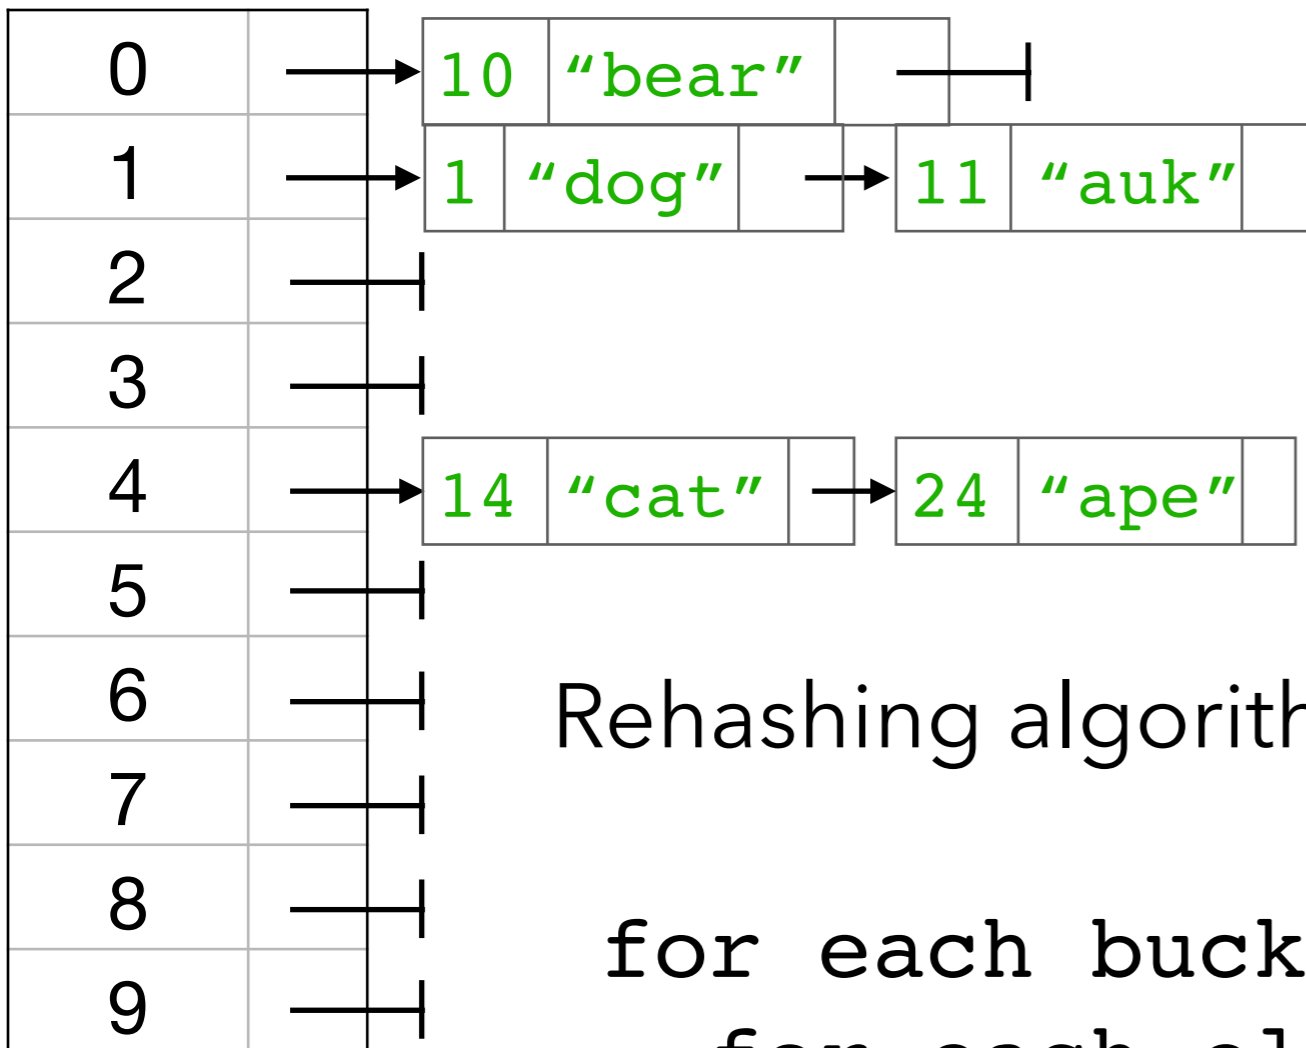

$$(24 \% 3) \rightarrow 0$$

Rehashing: Runtime, take 1

Let C = array size

Let n = number of entries

Overall runtime is:

- worst-case $O(C + n^2)$
- average-case $O(C + n)$

visits C buckets

Rehashing algorithm:

visits n entries (total)

could be $O(n) =$

for each bucket b :

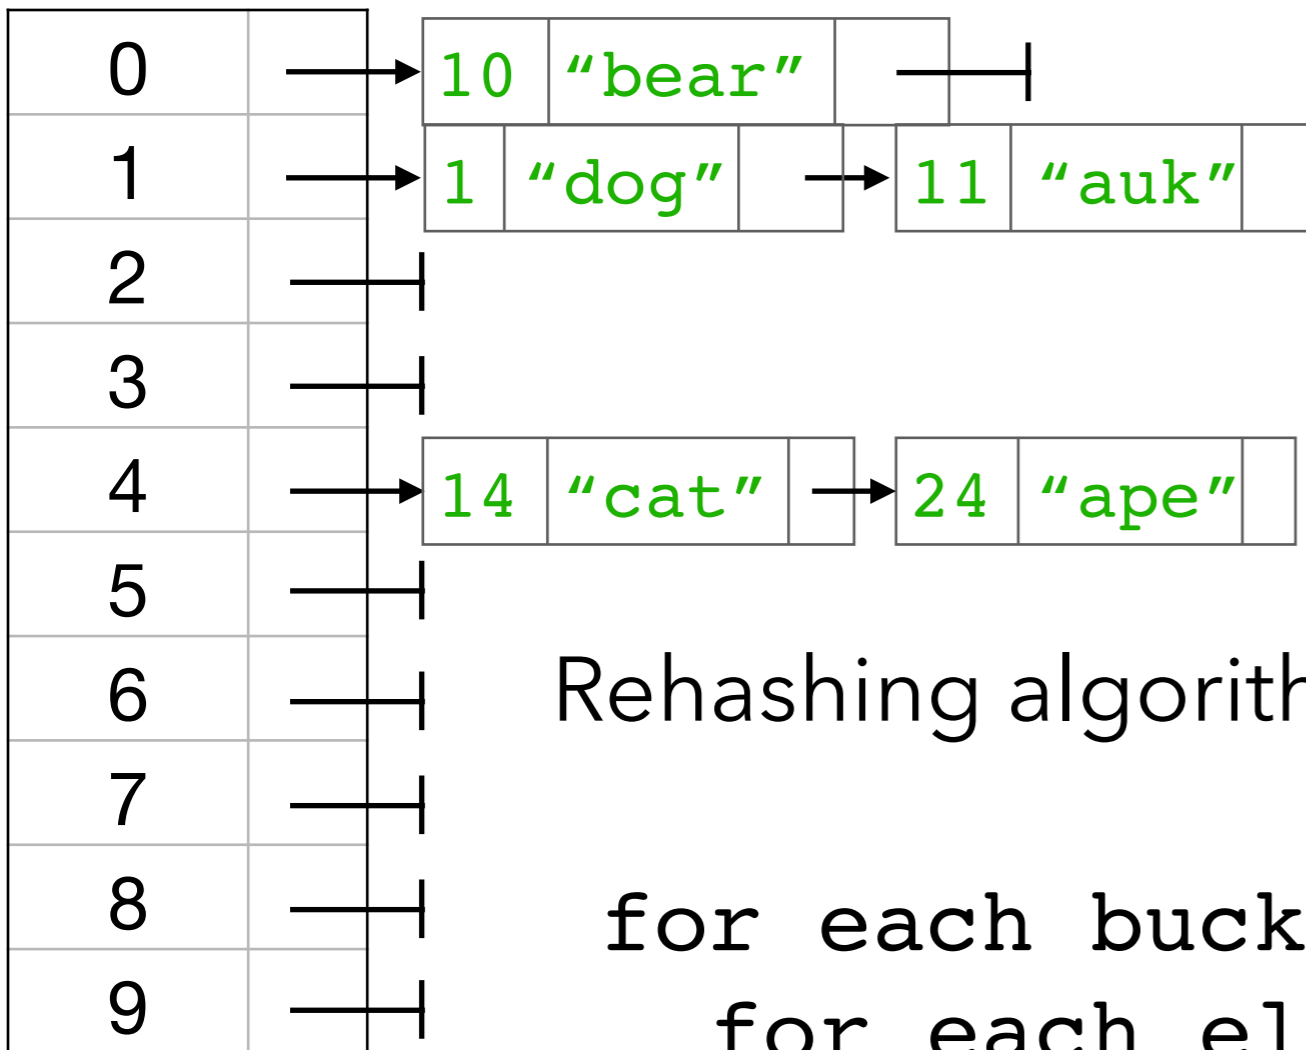

for each element e in b :

put e into the new array

Rehashing: Runtime, take 2

Let C = array size

Let n = number of entries

Overall runtime is:

- worst-case $O(C + n)$

visits C buckets

Rehashing algorithm: ↓ visits n entries (total)

could it be $O(n)$?

for each bucket b : ↓

for each element e in b : ↓

put e into the new array

put is $O(n)$ because it has to search for existing keys.

Here, we **can't** have duplicate keys: all entries were already in the map!

Consequence: we don't need to search the bucket when rehashing
